In-Class Assignment 4

1. **Sales lead scoring.** A model assigns potential customers a score indicating their likelihood of purchasing a product sellers need to sell. Sales representatives decide which leads to contact. Representatives receive commissions for completed sales.
 - How will representatives probably use the scores?
 - Which customers might stop receiving attention?
 - Does maximizing probability of sale necessarily maximize incremental value?
 - Could the model change salesperson behavior enough to change the data used to retrain it?
 - What should happen when a salesperson disagrees with a score?
 - What information should be collected about leads that were never contacted?

2. **Inventory shortage predictions.** A retailer predicts which products are likely to experience shortages. Store managers can request additional inventory from a limited central supply. Managers know that other stores are receiving the same predictions.
 - What will a store manager do after receiving a high shortage probability?
 - What happens if every manager requests extra inventory?
 - Is there an incentive to exaggerate local need?
 - Should stores compete for inventory or should allocation be centralized?
 - What information should headquarters reveal to stores?
 - How should the prediction system interact with the allocation process?
